

Reward on the terminal state: $P_\sigma(t_n, t_p)$, probability of mRS 0–1 at 90 days given onset-to-needle t_n and onset-to-puncture t_p .
First decision maximizes $\sum_\sigma p_\sigma [R(s, a_1, s'_\sigma) + \max_{a_2} R(s'_\sigma, a_2, s''_\sigma)]$; **second decision** is made with σ known. At most one transfer.
